Fluid

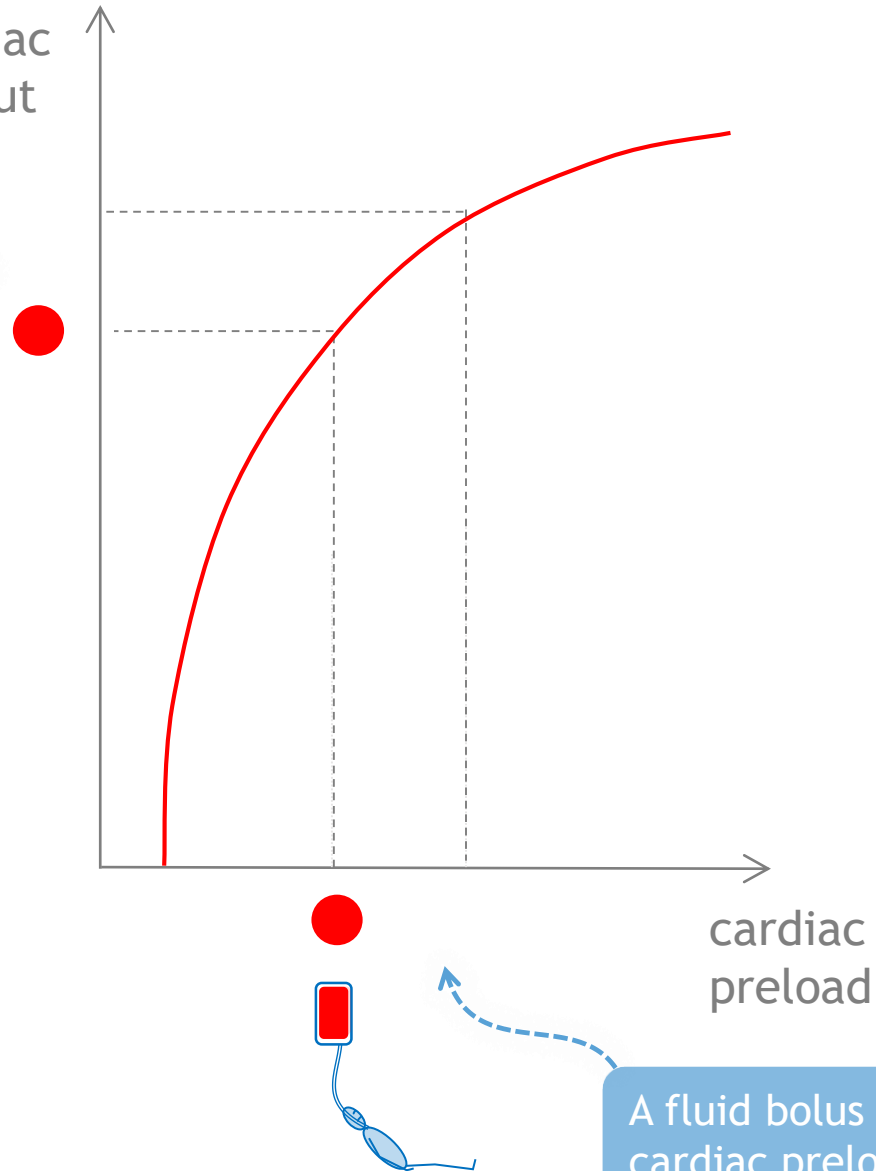

Why do we give fluid to shock patients ?

... in order to increase cardiac output

cardiac output

BUT !!!!

A fluid bolus increases cardiac preload...

What is the concept ?

Let's go back to physiology !

GUIDELINES

Surviving sepsis campaign: international guidelines for management of sepsis and septic shock 2021

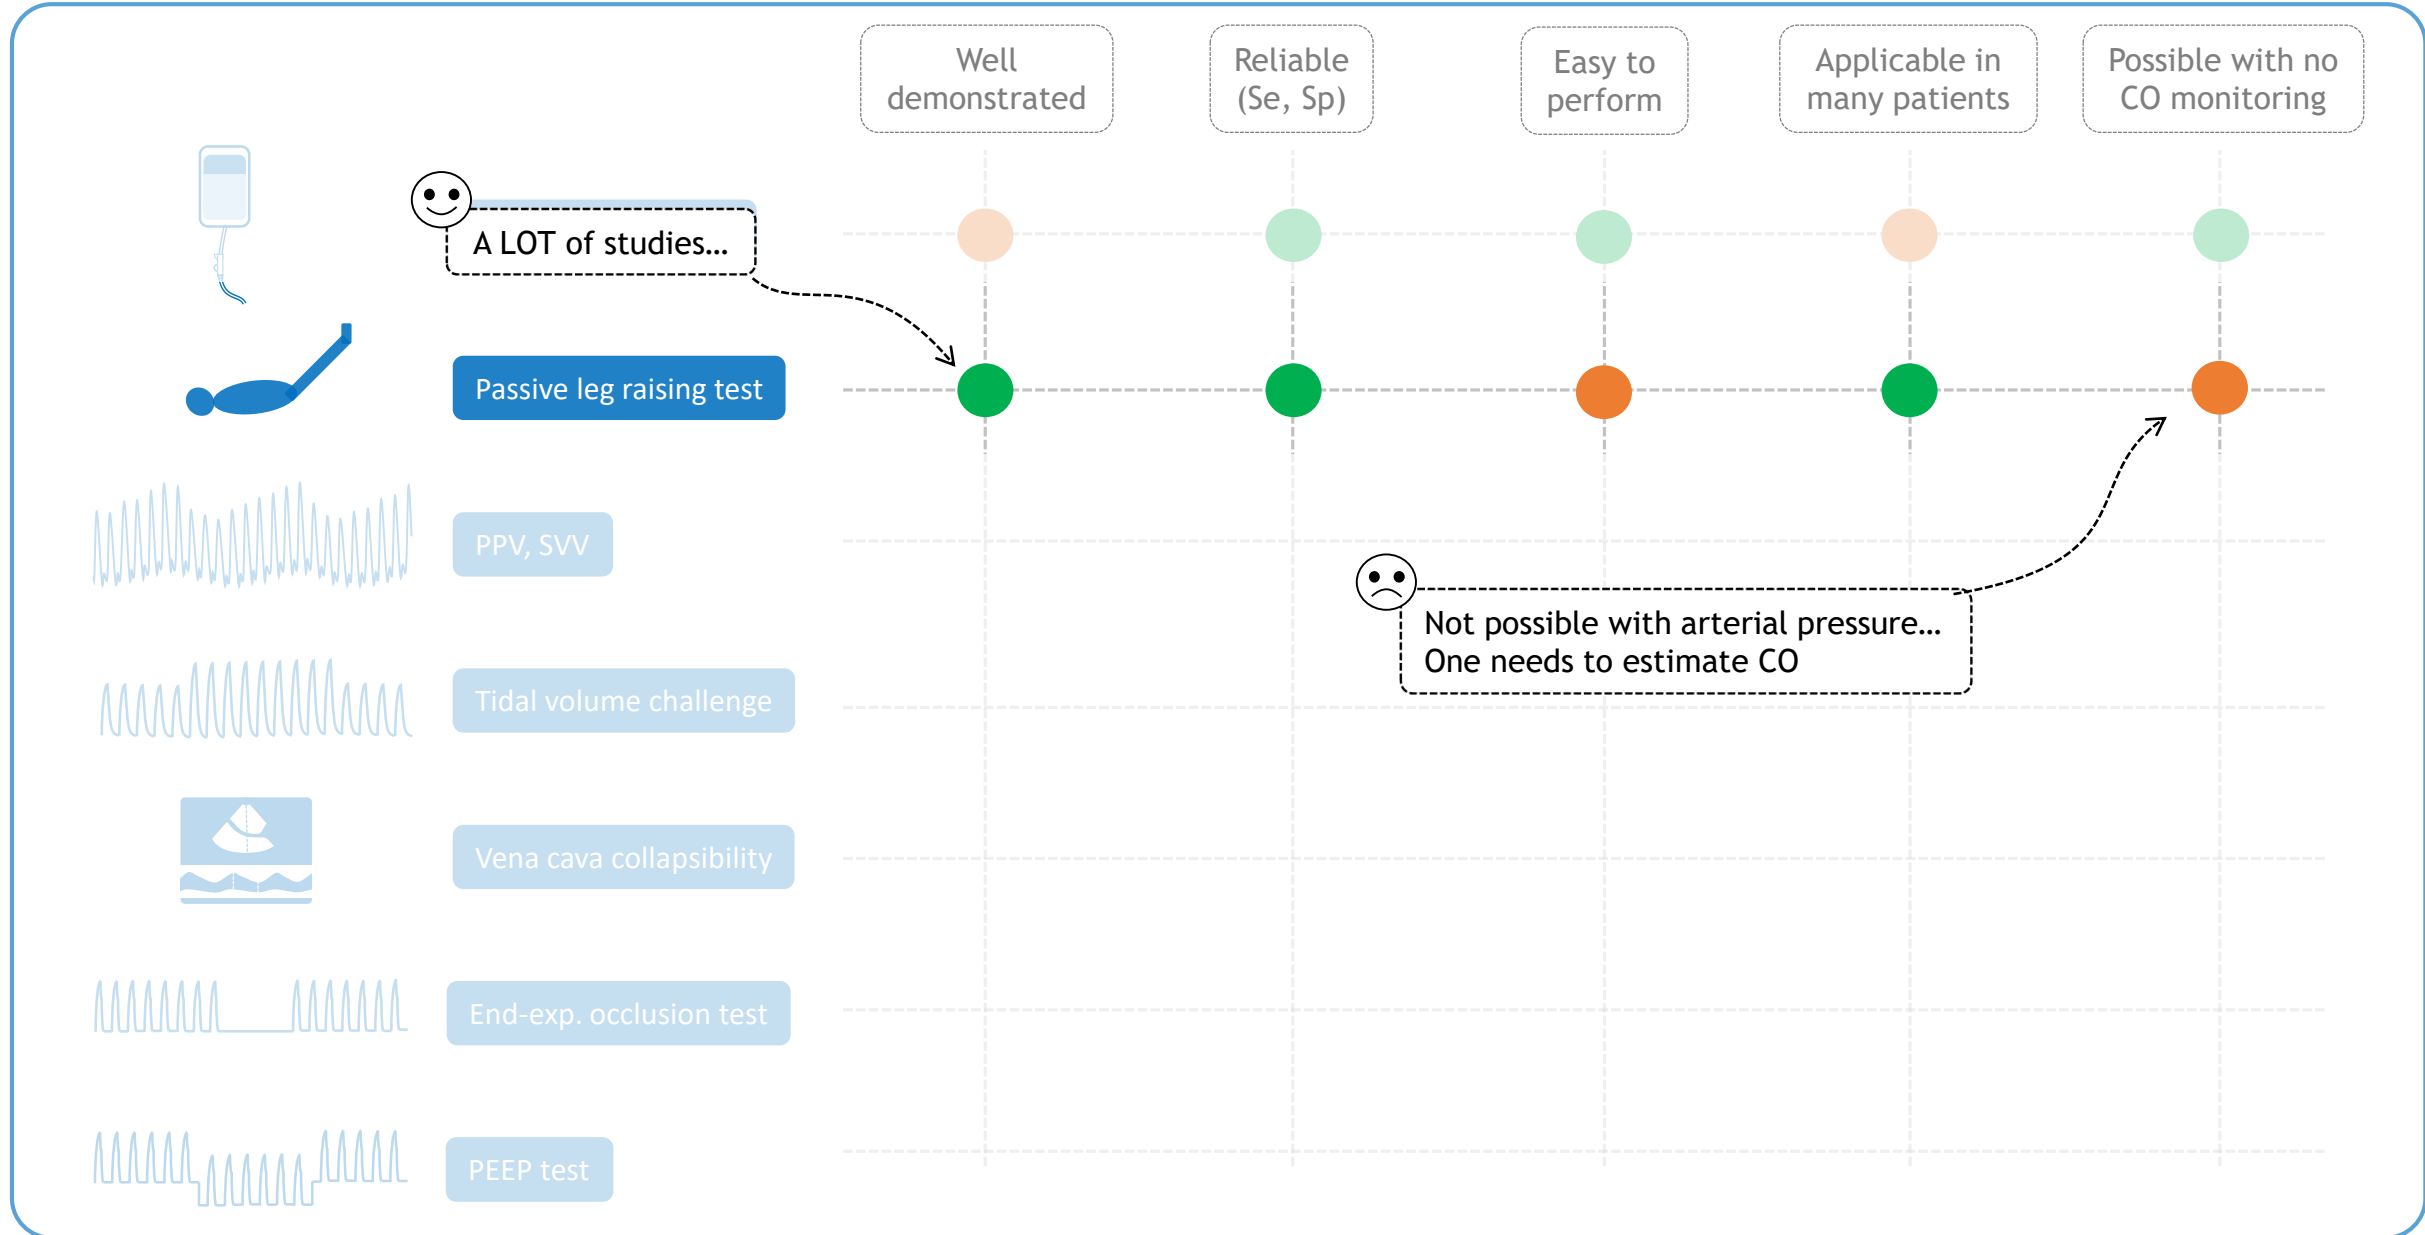

Most patients require continued fluid administration following initial resuscitation. Such administration needs to be balanced with the risk of fluid accumulation and potential harm associated with fluid overload, in particular, prolonged mechanical ventilation, acute kidney injury (AKI). The most important principle for fluid management in septic patients is the need for ongoing re-evaluation to avoid over- and under-resuscitation. Beyond the initial resuscitation, a careful assessment of fluid responsiveness is essential for adequate perfusion. Heart rate, stroke volume, and systolic blood pressure are indicators of fluid status. Dynamic measures include passive leg raising combined with cardiac output (CO) measurement, fluid challenges against stroke volume (SV), systolic pressure or pulse pressure, and increases of SV in response to changes in intrathoracic pressure. In a dynamic assessment with reduced mortality, length of stay (LOS), and duration of mechanical ventilation (CI=5.08 to -0.89) [3]. However, in the other meta-analysis, there was no significant difference in mortality between septic patients resuscitated with a volume

of fluid status. Dynamic measures have demonstrated better diagnostic accuracy at predicting fluid responsiveness compared with static techniques. Dynamic measures include passive leg raising combined with cardiac output (CO) measurement, fluid challenges against stroke volume (SV), systolic pressure or pulse pressure, and increases of SV in response to changes in intrathor-
